METHODS AND ARRANGEMENT IN AN INFORMATION MANAGEMENT
SYSTEM

Field of the Invention

The present invention relates generally to collecting and processing of information. More specifically, the invention concerns on demand generation of position-coded
5 bases and transmission of information recorded from such bases.

Background Art

Electronic pens can be used for generation of electronic information that reflects handwritten entries on a
10 base. It would be desirable to incorporate such electronic pens in an information management system such that the electronic information could be efficiently conveyed to different destination units for further processing.

15 In WO 01/48685, WO 01/48678 and WO 01/48591, which are herewith incorporated by reference, the present Applicant has suggested such information management systems in which a position code is applied to each base to code a plurality of absolute positions thereon. By
20 reading the position code, the electronic pens are capable of electronically recording a sequence of positions that reflect their own motion on the base.

The position code on each base is a subset of a much larger abstract position-coding pattern. Examples of such
25 abstract patterns are given in WO 01/26032, WO 00/73983 and WO 99/50787, which are herewith incorporated by reference.

The abstract pattern may be dynamically or statically divided into subsets of given size, each such
30 subset being associated in the system with a unique identifier. If each subset is intended for a respective physical page, it is denoted a logic page and is

represented by a unique page address. In such a case, each absolute position may be represented by a page address and a local position within the associated logic page.

5 By designating different parts of the abstract pattern to different destination units, the electronic information can be automatically directed from the pen to the correct destination unit for processing. For example, the system may include an intermediary server which, upon
10 receipt of one or more absolute positions from a pen, identifies an associated network address of the correct actor and directs the flow of data to this address.

It might be desirable to provide for on-demand generation of coded bases, e.g. by means of digital
15 printers, in an information management system of the above-identified type. Such systems are disclosed in Applicant's co-pending PCT application No. PCT/SE03/01643, which was unpublished at the filing of the present application and is herewith incorporated by
20 reference. These systems include a printing tool that allows a user to request the printing of an electronic document as a coded base. Upon such request, the printing tool obtains a subset of the abstract pattern from a position assigner. The position assigner also provides
25 electronic allocation data in the system which allows the intermediary server to direct the flow of data to the correct network address.

There is a need to provide, in such a print on demand system, a technique to designate parts of the
30 coding pattern efficiently, transparently and in real time.

Summary of the Invention

It is an object of the present invention to fulfill the above-mentioned need.

35 This and other objects, which will be evident from the following description, are achieved wholly or partly by methods and an arrangement for allotting pattern units

of an overall coding pattern as set forth in the independent claims. Preferred embodiments are defined by the dependent claims.

Brief description of the drawings

5 Presently preferred embodiments of the invention will be described in more detail below with reference to the accompanying drawings.

Fig. 1 shows the hierarchical organization of pattern pages of an abstract position-coding pattern.

10 Fig. 2 shows an information management system based on the position-coding pattern of Fig. 1, including components for on demand printing of coded products.

Fig. 3 shows the allowed state transitions for the pattern pages in the system of Fig. 2.

15 Figs 4A-4C illustrate examples of allotment tables used in the system of Fig. 2.

Fig. 5 illustrates yet another example of an allotment table.

20 Fig. 6 shows an arrangement for allotting pattern pages in the system of Fig. 2, together with interfacing devices.

Description of preferred embodiments

The following description is based on the use of the above-identified abstract position-coding pattern, which is subdivided into page units. The page units can be arranged in a hierarchy of superordinate subsets of the pattern. Fig. 1 shown an example, in which the pattern 106 contains "segments" 110 which in turn are divided into a number of "shelves" 111, each containing a number of "books" 112 which are divided into a number of aforesaid page units 113, also called "pattern pages".

Suitably, all pattern pages have the same format within one level of the above pattern hierarchy. For example, some shelves may consist of pattern pages in A4 format, while other consists of pattern pages in A5 format. The position of a certain pattern page in the abstract pattern can be noted as a page address of the form:

segment.shelf.book.page, for instance 99.5000.1.1500,
more or less like an IP address. For reasons of process-
ing efficiency, the internal representation of the page
address may be different, for example given as an integer
5 of a predetermined length, e.g. 64 bits.

In one example, each segment consists of more than
26,000,000 pattern pages, each with a size of about 50x50
cm². In one embodiment, at least one such segment is
divided into 5,175 shelves, each consisting of 2 books
10 with 2,517 pages each.

Each pattern page may be regarded as an actual sub-
set of the coding pattern, or as the absolute positions
that are coded by the subset. Each such absolute position
may be represented as a global position in the coordinate
15 system of the overall pattern, or as a page address and a
local position within the corresponding pattern page.

The following description is also based on each
product containing position code that corresponds to one
or more pattern pages. It is to be noted, however, that
20 the position code on a product need not conform with a
pattern page. Thus, one or more subsets from one or more
pattern pages may be arbitrarily arranged on the product.
The product may also contain functional areas that each
is associated with a particular function to operate on
25 any pen strokes therein.

Each product is represented by a definition file
(PAD file) which identifies the page address(es) of the
relevant pattern page(s), and defines the mapping of the
pattern page(s) on the product, the placement and size of
30 each functional area on the pattern page(s), as well as
the associated function. Each product is also represented
~~by a graphics file which defines the human-readable~~
information on the product, i.e. the layout, which aims
at instructing, controlling and/or informing a user.

35 An electronic pen may record its motion on a
position-coded product as a page address and a sequence
of local positions on the corresponding pattern page.

Thus, a physical pen stroke is recorded as an electronic pen stroke in the form of a sequence of positions.

Fig. 2 illustrates an information management system with print on demand capability. A printing tool 200, in the form of a dedicated software module 202 which is executed on a personal computer, communicates with a repository 204 which stores graphics files available for printing. The printing tool also communicates with an assigner 206, which has access to a database 208 that represents at least part of the abstract pattern, and a digital printer 210.

The system also includes a flow controller 216, here embodied as a router, which communicates with electronic pens 214 to direct the flow on data to one of several destination units 218.

The repository 204, the assigner 206 and the flow controller 216 are typically network-connected computers with software which, when executed in an internal processor, implement the processes that are performed in the respective units. Likewise, each destination unit 218 is typically a network-connected computer with software that implements one or more services that operate on the information that is recorded with an electronic pen on one or more service-related position-coded products.

Via the printing tool 200, a user may select one of the graphics files in the repository 204 for printout. The printing tool then contacts, automatically or on command, the assigner 206 with a request for pattern data. The request may contain an indication of number of pages, number of printout copies, page format (e.g. A4, A3, B4, Letter), etc. Optionally, the indication of the number of pages and/or page format can be replaced by the graphics file being included in the request. Alternatively, the number of pages and/or the page format and/or the number of printout copies are given by standard settings in the assigner 206.

As will be described in further detail below, the assigner 206 then allots one pattern page for each physical page and each printout copy in the request. The assigner also maintains allocation data, which ultimately
5 identifies the appropriate destination unit 218 to receive any information that is recorded from the respective pattern page.

In response to the request, the assigner 206 returns assignment data corresponding to the allotted pattern
10 page(s). In the example below, the assignment data includes one or more page addresses. Alternatively, the assignment data may comprise either of two opposite corner positions for the respective pattern page, a file with an algorithm for generating a corresponding position
15 code, or a file containing a corresponding position code. The assignment data may alternatively be represented by a single global position, after which the printing tool 200 can compute the other positions for the allotted pattern page, if the size of the pattern page is known.

20 The printing tool 200 then compiles a graphics layer, which is given by the graphics file, and a coding layer, which is given by the assignment data, in a printout file which is sent to the printer 110 for printing on a suitable substrate, such as paper, plastic,
25 laminate, etc. Alternatively, this compiling takes place in the printer itself, which also may send the request for pattern data to the assigner 206. In certain cases, access to the PAD file may be necessary for the compiling of the coding layer. To this end, the PAD file can be
30 stored in the repository 204 to be accessible to the printing tool 200. Alternatively, relevant information
~~from the PAD file may be incorporated into the graphics~~
file.

The resulting position-coded product 212 is then
35 distributed to a user, who writes thereon with an electronic pen 214. The pen is subsequently caused to send an address query to the router 216 at a

predetermined network address. The address query may contain one or more absolute positions (global position or page address) that have been decoded from the product. The router receives the address query and identifies the
 5 network address of the appropriate destination unit 218. This may take place via a corresponding query to the assigner 206 to derive the allocation data which, directly or indirectly, connects the received absolute position to the network address.

10 For example, each graphics file may have a unique identity (document identifier; docID) in the system, which is registered in the router 216 in association with the network address of the destination unit. If the printing tool 200 conveys the document identifier to the
 15 assigner 206, suitably in connection with the request for pattern data, the assigner may store an association between each allotted pattern page and the corresponding document identifier.

Thus, the router 216 is capable of returning a reply
 20 message with the current network address to the pen 214, which may connect to this address and transfer some or all of the absolute positions that it has detected on the product 212.

The principles, operation and structure of the
 25 assigner will now be further described with reference to Figs 3-6.

The assigner 206 operates with four different possible states of the pattern pages in the database 208. As indicated in Fig. 3, all pattern pages are initially
 30 designated as "Free".

The "Free" state may be changed to an "Allotted" state, indicating that the pattern page has been allotted

 for printing. Such a pattern page is blocked from further allotment.

35 The "Allotted" state may be changed to a "Released" state, either automatically, for example a predetermined time after the transition to the "Allotted" state, or

upon external request, e.g. by a destination unit. In the "Released" state, the related pattern page is again available for allotment, at least after a predetermined time has elapsed since the transition to the "Released" state. Upon such allotment, the "Released" state is changed to the "Allotted" state.

The "Allotted" state may also be changed to a "Locked" state, in which the allocation data is made inaccessible to the router 216, to thereby block any transfer of information from the related pattern page in the system. The transition "Allotted" to "Locked" may be effected upon external request, e.g. by a destination unit. For example, the destination unit may only allow information to be conveyed from a pattern page a given number of times.

The "Locked" state may be changed back to the "Allotted" state, either automatically, for example a predetermined time after the transition to the "Locked" state, or upon external request, e.g. by a destination unit. Thus, a destination unit can control the use of a given pattern page, for example to provide version control.

The "Locked" state may also be changed to the "Released" state, again upon external request, e.g. by a destination unit.

All requests for state change from an external unit to the assigner may have to be supplemented by authentication data, for example, an identifier (name/address) and a password.

The allotment of pattern pages can be effected according to different principles. In one embodiment, the adequate number of pattern pages for each printout copy is picked out as a set of consecutive pages, given by the page addresses. This principle may result in a more efficient use of the database 208 (Fig. 2), with respect to storage capacity and/or search speed. It may also be preferable that the pattern pages allotted to each

printout copy all belong to one and the same book in the pattern hierarchy. It may also be preferable that all pattern pages that have been allotted to one and the same printout copy have their states changed simultaneously.

- 5 For example, the whole copy of a printed document will be locked for use with the electronic pen if a request for locking of one of the related pattern pages is sent to the assigner, and vice versa in the case of a request for un-locking (transition to "Allotted" state).

10 It may not be necessary to make use of all the states described above. In one simple example, only the "Free" and "Allotted" states are used. The assigner may have access to a parameter that designates the last pattern page ("Max Page Address") that was allotted in
15 the last request. Upon receiving a request for pattern data, the assigner may operate according to:

1. Read document identifier from request;
2. Read number of copies from request;
- 20 3. Obtain current Max Page Address;
4. For each copy:
 - 4a. Add requested number of pages to Max Page Address to form new Max Page Address;
 - 4b. If new Max Page Address exceeds book limit,
25 restart allotment on first pattern page in next book and form new Max Page Address;
5. Return page addresses for all allotted pattern pages;
6. Store association between the document identifier and the page addresses of the allotted pages.

30

The association may for example be stored in an allotment table as shown in Fig. 4A. In this example, the allotment table only lists the pattern pages in the "Allotted" states (designated by "A"), and contains one
35 record per allotted page. The above parameter "Max Page Address" could be obtained from the last record in this table. The table is also searched by the assigner to

retrieve and output a document identifier (docID) upon a request for allocation data from a router in the system.

In a more advanced example, enabling use of all the above states, the assigner operates according to:

5

1. Read document identifier from request;
2. Read number of pages from request;
3. Read number of copies from request;
4. For each copy:
 - 10 4a. Search allotment table to identify a suitable block of pages in "Released" state;
 5. If there are not enough suitable blocks of pages in the allotment table, missing blocks are allotted from "Free" pages according to the first example above;
 - 15 6. Return page addresses for all allotted pattern pages;
 7. Store association between the document identifier and the page addresses of the allotted pages.

Each suitable block of pages is a set of consecutive
 20 pattern pages within one book, the number of pages being at least equal to the requested number of pages for each copy.

In the above example, the allotment process prioritizes "Released" pages over "Free" pages, i.e. since this
 25 will result in fewer records in the allotment table for the same number of allotted pages.

Often, there are many suitable blocks of "Released" pages in the allotment table. The selection of one of many suitable blocks could be based, for example, on any
 30 one of the following algorithms, or combinations thereof:

- A. First fit, in which the allotment process selects the first block large enough to satisfy the request.
- B. Best fit, in which the allotment process always selects the smallest suitable block.
- 35 C. Worst fit, in which the allotment process always selects the largest suitable block.

D. Next fit, in which the allotment process resumes searching where the previous one ended.

E. LIFO-ordered first fit, in which the allotment process always selects the most-recently released
5 suitable block.

F. FIFO-ordered first fit, in which the allotment process selects the least recently released suitable block.

Algorithm A may be advantageous for reasons of
10 processing speed. Algorithm B may be advantageous when the allotment requests are similar in size (with respect to the number of requested pages per copy). Algorithm C may be advantageous when the allotment requests are dissimilar in size.

15 In allotting "Free" pages (step 5 of the second example above), whenever a requested block of pages for a printout copy does not fit within a current book, the allotment is restarted on the first page in the next book, but the remaining pages in the current book are
20 nevertheless entered into the allotment table with the state set to "Released". Thereby, these left-over pages are made available for future allotment.

Fig. 4B illustrates another example of an allotment table, which contains one record per allotted page. The
25 AllotmentID field indicates all pages that are allotted to one and the same printout copy. The PageCount field indicates the number of pages available within one allotment (given by the AllotmentID), with the first record thereby indicating the number of consecutive
30 records that belongs to the same allotment.

After an allotment request for one printout copy of
three pages, the allotment table would be searched for
records with State=R and PageCount>=3. After allotment,
the table of Fig. 4B would be updated, resulting in the
35 table of Fig. 4C.

Over time, the allotment table will become more and more fragmented, resulting in reduced performance and

poor economization of the abstract pattern. Therefore, a defragmentation process is intermittently effected, in which the allotment table is processed to merge adjacent records of "Released" pages. Thus, the defragmentation process results in larger blocks of released pages being made available for allotment. For example, in the table of Fig. 4B, the defragmentation results in an update of the *PageCount* field, as well as a cancellation of the *AllotmentID* and *docID* fields, as shown in Fig. 4D.

10 According to one alternative, all records that are changed from an "Allotted" state to a "Released" state are deleted from the allotment table. Possibly, the deletion is effected a predetermined time period (quarantine period) after the transition to the "Released" state. In essence, such deleted records are set in the "Free" state. In this case, the allotment process may be implemented to locate the suitable blocks as gaps in the allotment table. To reduce the processing intensity and/or increase the processing speed, a field in the allotment table may indicate the number of subsequent "Free" pages. Further, the allotment process may be implemented to search for the suitable blocks in a second allotment table that contains the "Free" pages resulting from deletions in the basic allotment table.

25 Still further, the allotment table may include additional fields, for example *TimeAllotted*, *TimeLocked*, *TimeReleased*, which may be used in the searching of the table and/or in the changing of states.

As a further alternative, the allotment table may include one record for each printout copy, instead of one record for each allotted pattern page, resulting in a more compact database representation. An example of such an allotment table is shown in Fig. 5, in which a *PageCount* field indicates the number of pattern pages included in each record. In the case of large print jobs, it is conceivable that entire books are being allotted (batch allocation). For reasons of searching efficiency,

the table of Fig. 5 also includes a *BookCount* field to indicate the number of complete books included in each record.

In the event of a request for allocation of *p* pages, the allotment process searches the allotment table for records having a *PageCount* $\geq p$ and a *State*=R, selects one such record (e.g. subject to any of the above selection algorithms A-F), and changes the state to "A". If the *PageCount* of the selected record exceeds *b*, the allotment process creates a new record for the surplus pages with the state set to "R". If no suitable records are found in the allotment table, the allotment process obtains the parameter "Max Page Address", and allots free pages. The parameter "Max Page Address" may be given by the last page of the record with the largest page address in the allotment table, optionally with the constraint *BookCount*=0.

The allotment process for a batch allocation of *b* books is effected analogously to the above, albeit based on *BookCount* instead of *PageCount*.

The table of Fig. 5 also includes a *LastAddress* field, which may facilitate both the above identification of the "Max Page Address", and the identification of allocation data upon a request from the router. In the latter case, a lookup for a given page address *PA* involves finding the record for which *PA* \geq *PageAddress* and *PA* \leq *LastAddress*.

The above defragmentation process may analogously be effected on the compact representation of Fig. 5.

In a further variant, the allotment table comprises a *FormInstanceID* field which may hold a form instance identifier (printID) that contains characters and/or numbers with an arbitrary base. This printID may be generated by the printing tool to uniquely identify a specific printout of a graphics file. The printing tool may include the printID in the request for pattern data to the assigner, which may then store an association

between the printID and the allotted pattern pages, via the *FormInstanceID* field.

The printID may be used to identify printout-specific data to be accounted for by the destination unit when processing information recorded from a specific printout. Alternatively or additionally, the printout-specific data may be included in the graphics layer of the printout. In the former case, the destination unit may include a received page address in a request for printID which is sent to the assigner. In response to such a request, the assigner may locate a corresponding record in the allotment table, and output the printID given by the *FormInstanceID* field of that record. The destination unit may then use this printID as is, or use the printID as a key to derive further instance data from a suitable database. For example, the printID may be an employee number which can be used by the receiving destination unit to fetch additional information about that employee, such as an address, a company affiliation, a bank account number, etc.

It should be clear that the allotment table can be implemented in any type of data structure which allows for efficient searching and which is easy to extended, for example a table, a tree, etc. For example, the allotment table may be implemented in a relational database, with Structured Query Language (SQL) being used for making interactive queries to and updating the database. Alternatively, the allotment table may be implemented in an object-oriented programming database.

In the embodiment of Fig. 6, the assigner 600 includes a memory 602 (e.g. a hard disk, RAM, flash, etc) which holds the allotment table, and a processor 604 (e.g. a microprocessor, CPU, ASIC, FPGA, etc) which executes the processes of the assigner. The assigner has a number of interfaces. A first interface 606 for dynamic pattern allocation allows an interfacing unit, e.g. the printing tool 200 (Fig. 2), to request one or more

pattern pages and to obtain the corresponding assignment data. A second interface 608 for handling of allotted pattern allows an interfacing unit, e.g. a destination unit 218 (Fig. 2), to request locking (Allotted →
 5 Locked), un-locking (Locked → Allotted) or releasing (Allotted/Locked → Released) of one or more pattern pages, as given by their page addresses. The second interface 608 also allows the interfacing unit to request a form instance identifier, based on a page address. A
 10 third interface 610 for allocation data allows an interfacing unit, e.g. the router 216 (Fig. 2), to request and obtain a document identifier based on a page address. A fourth interface 612 for administration allows a system administrator to view and edit the allotment
 15 table, to update the implementing software of the assigner, to initiate a defragmentation process, to selectively or collectively release (Allotted/Locked → Released) one or more pattern pages, to obtain database statistics, such as the number of "Allotted", "Free",
 20 "Released" and "Locked" pattern pages, etc.

At least some of these interfaces may be implemented as web services using the Simple Object Access Protocol (SOAP). The web services may be described in the Web Services Description Language (WSDL).

25 The system of Fig. 2 may include more than one assigner. For reasons of access and security, a sub-system including an assigner may be tailored to a specific company. Ideally, each such sub-system should operate on an exclusive part of the abstract pattern. In
 30 practice, however, there may be several sub-systems operating at least partly on the same part of the abstract pattern. In the case of a merger between two such companies, their sub-systems should also be merged to avoid confusion. To minimize conflicts and erratic
 35 behavior of the resulting sub-system, a set of state rules are applied pattern page by pattern page when importing an allotment table from a first assigner into a

second assigner, for example via the fourth interface 612 (Fig. 6). The following rules designate the state in the first assigner, the state in the second assigner, and the resulting state of the pattern page after merging. The
 5 symbol * designates any one of the available states.

Allotted + Free = Allotted
 Allotted + Allotted = Locked
 Allotted + Locked = Locked
 10 Allotted + Released = Allotted
 Locked + * = Locked
 Released + * = *
 Free + * = *

15 There are many variations that may be made consistent with the present invention. The foregoing description is presented for purposes of illustration and description. It is not exhaustive and does not limit the invention to the precise form disclosed. Modifications
 20 and variations are possible in light of the above teachings or may be acquired from practicing the invention.

In the above embodiments, the "Free" state is implicit in the allotment table, whereas the "Allotted", "Released" and "Locked" states are explicitly recorded.
 25 Of course other permutations are conceivable, in which one state is implicit and the other states explicitly recorded in the table. Records in the "Allotted" state are preferably explicitly recorded since they contain the allocation data used by the router. In a further alterna-
 30 tive, the allotment table may explicitly record all states of all page addresses of the relevant part of the abstract pattern. Further, the allotment table may be distributed over any plurality of sub-tables.

Instead of locating suitable blocks of consecutive
 35 pages, the allotment process may use any other principle, for example allotting the first pattern pages that are

available in the allotment table irrespective of block size.

In a further alternative, where different shelves or books consist of pattern pages of different format, the
5 allotment process is directed to the adequate shelves and books dependent on format information included in the request for pattern data from the printing tool.

It may also to be noted that the allocation data may take any form. In one alternative, the allocation data
10 directly associates each page address with the appropriate network address of the destination unit. Further alternative formats of the allocation data are given in aforesaid PCT application No. PCT/SE03/01643.

The drawings illustrate the repository, the
15 assigner, and the router as separate physical units. Such a modular construction may be preferred for reasons of administration or manufacture. However, it is possible to implement at least some of them in one and the same physical unit, for instance in order to reduce delays in
20 the system. According to one alternative, the repository and the assigner may be combined in one and the same physical unit. According to another alternative, the assigner and the router may be combined in one and the same physical unit.

CLAIMS

1. A method of allotting pattern units of an overall coding pattern in an information management system, in
5 which each pattern unit has a unique pattern address, said method comprising:
 receiving an allotment request for a number of pattern units;
 searching an electronic representation of said
10 overall coding pattern to locate said number of pattern units available for allotting;
 setting a state indicator of said number of pattern units in said representation to indicate an allotted state; and
15 outputting an indication of the pattern addresses of said number of pattern units.
2. The method of claim 1, wherein the pattern units are defined in an ordered sequence by the pattern addresses, said searching comprising: locating said
20 number of pattern units as consecutive pattern units in said ordered sequence.
3. The method of claim 1 or 2, wherein said pattern units are divided into ordered groups, said searching comprising: locating said number of pattern units within
25 one of said groups.
4. The method of any preceding claim, further comprising: selectively changing the state indicator of at least one pattern unit from the allotted state to a released state.
- 30 5. The method of claim 4, wherein said changing is effected based on an elapsed time since the state indicator was set to the allotted state.
6. The method of claim 4 or 5, wherein said changing is effected based on receipt of a request for release.
- 35 7. The method of any one of claims 4-6, wherein said released state indicates that the pattern unit is available for allotting.

8. The method of claim 7, wherein said released state indicates that the pattern unit is available for allotting a predetermined time after the state indicator was set to the released state.

5 9. The method of any one of claims 4-8, wherein said searching is at least partly based on the state indicator.

10 10. The method of claim 9, wherein said searching comprises a re-use step in which searching is effected among pattern units with the state indicator in the released state.

15 11. The method of claim 10, wherein said searching comprises, if the re-use step is unsuccessful: locating said number of pattern units among previously un-allotted pattern units in said representation.

12. The method of any preceding claim, further comprising: selectively changing the state indicator of at least one pattern unit from the allotted state to a locked state.

20 13. The method of claim 12, wherein said locked state indicates that information relating to the pattern unit is to be blocked from being transferred in said information management system.

25 14. The method of claims 12 or 13, further comprising: selectively changing the state indicator of at least one pattern unit from the locked state to the allotted state.

30 15. The method of any one of claims 12-14, further comprising: selectively changing the state indicator of at least one pattern unit from the locked state to a released state.

16. The method of claim 15, wherein said changing is effected based on an elapsed time since the state indicator was set to the locked state.

35 17. The method of claims 4, 12, 14 or 15, wherein said changing is effected based on receipt of a request

for state change indicating the pattern address of each pattern unit to be affected.

18. The method of any previous claim, wherein said searching is effected in a data structure containing at least part of the electronic representation, said data structure comprising a set of records, each record comprising a pattern address field and a state indicator field.

19. The method of claim 18, wherein each record represents one allotment request.

20. The method of claim 18, wherein each record represents pattern units that have been allotted to a set of pages of an electronic document.

21. The method of claim 19 or 20, wherein each record comprises a field that indicates the number of allotted pattern units.

22. The method of claim 18, wherein each record represents one pattern unit.

23. The method of any one of claims 18-22, wherein said setting of the state indicator comprises deleting a record from said data structure.

24. The method of any one of claims 18-23 in combination with any one of claims 4-11, wherein the representation comprises an ordering of the pattern units as defined by the pattern addresses, said method further comprising: locating, in said data structure, records that have both a state indicator field in the released state and adjacent pattern addresses in said ordering, and merging such records.

25. The method of any previous claim, further comprising: deriving at least one destination identifier from said allotment request, and storing the destination identifier in association with the pattern addresses of said number of pattern units.

26. An arrangement for allotting pattern units of an overall coding pattern in an information management system, said arrangement comprising:

a storage which contains an electronic representation of the overall coding pattern;

a first interface;

a processing unit which comprises:

5 means for receiving, on the first interface, an allotment request for a number of pattern units;

 means for searching said representation in the storage to locate said number of pattern units available for allotting;

10 means for setting a state indicator of said number of pattern units in said representation to indicate an allotted state; and

 means for outputting, on the first interface, an indication of the pattern addresses of said
15 number of pattern units.

27. The arrangement of claim 26, wherein said system comprises a generation tool which coordinates the generation of a product with a coding layer that is based on said number of pattern units, said first interface being
20 adapted for communication with said generation tool.

28. The arrangement of claim 26 or 27, further comprising a second interface, wherein the processing unit comprises means for receiving, on the second interface, a request for state change indicating the pattern
25 address of each pattern unit to be affected.

29. The arrangement of claim 28, wherein data is selectively transferred in said system to a plurality of destination units, said second interface being adapted for communication with the destination units.

30 30. The arrangement of any one of claims 26-29, wherein the processing unit further comprises means for receiving, on the first interface, at least one data identifier which is associated with the allotment request; and means for storing the data identifier in
35 said representation in association with said number of pattern units.

31. The arrangement of claim 30 in combination with claim 28 or 29, wherein the processing unit further comprises means for receiving, on the second interface, a data identifier request indicating at least one pattern address; means for identifying a data identifier in said representation based on the pattern address; and means for outputting, on the second interface, the thus-identified data identifier.

32. The arrangement of any one of claims 26-31, wherein the processing unit further comprises means for selectively changing the state indicator of at least one pattern unit from the allotted state to a locked state.

33. The arrangement of claim 32, wherein the locked state indicates that information relating to the pattern unit is to be blocked from being transferred in said system.

34. The arrangement of claim 32 or 33, wherein the processing unit further comprises means for selectively changing the state indicator of at least one pattern unit from the locked state to the allotted state.

35. The arrangement of any one of claims 26-34, wherein the processing unit further comprises means for selectively changing the state indicator of at least one pattern unit to a released state which indicates that the pattern unit is available for allotting.

36. The arrangement of any one of claims 26-35, wherein the processing unit further comprises means for receiving, on the first interface, at least one destination identifier; and means for storing the destination identifier in association with the pattern addresses of said number of pattern units.

37. The arrangement of claim 36, further comprising a third interface, wherein the processing unit comprises means for receiving, on the third interface, a destination identifier request indicating at least one pattern address; means for identifying a destination identifier in said representation based on the pattern address; and

means for outputting, on the third interface, the thus-identified destination identifier.

38. The arrangement of claim 37, wherein said system comprises a flow controller which directs data associated
5 with at least one of said pattern units to one of a plurality of destination units, said third interface being adapted for communication with said flow controller.

39. An information management system, comprising a
10 generation tool which coordinates the generation of a product with a coding layer that is based on a number of pattern units; a flow controller which directs data recorded by an electronic pen on the product to one of a
plurality of destination units, said data being asso-
15 ciated with at least one of said number of pattern units; and the arrangement of any one of claims 26-38.

40. A method in an information management system which controls the flow of data from an electronic pen to one of a plurality of destination units, said data being
20 associated with a position-coded product, said method comprising: allotting at least one pattern unit of an overall coding pattern for the generation of said position-coded product; selectively setting a state indicator for each allotted pattern unit to indicate one
25 of a plurality of states; and controlling the flow of data in said system based on the state indicator.

ABSTRACT

An arrangement and method of allotting pattern units of an overall coding pattern in an information management system, are based on selectively setting a state indicator for each pattern unit to indicate one of a plurality of states, and controlling the flow of data in said system based on the state indicator. The data may be originally recorded by an electronic pen from a coded product which is provided with at least part of a pattern unit. The product may be generated on demand by requesting an allotment of one or more pattern units.
